**Abstract:** The present work aims to investigate a green synthesis of AgNPs using *Muntingia calabura* leaf extract as reducing and stabilizing agents. The AgNPs formation was monitored using UV-Vis spectrophotometer. Characterisations of AgNPs size and shape were observed by TEM. The elemental analysis was analyzed using XDS. The maximum surface Plasmon resonance for AgNPs was detected at 425-430 nm. This study revealed that the AgNPs were polydispersed and polycrystalline nature. The microbial inhibition test against *Escherichia coli* and *Bacillus cereus* showed that the muntingia leaf-mediated AgNPs had inhibited the growth of these bacteria, as indicated by the formation of inhibition zone. The average inhibition zone for *Escherichia coli* was 10.3±0.5 mm and for *Bacillus cereus* at 9.5±0.6 mm. TEM results showed that the synthesised AgNPs have spherical form with the sizes ranging from 22 to 37 nm. Hence, the synthesised AgNPs can potentially be applied for water treatment and medicinal purposes.

**Keywords:** Green synthesis; silver nanoparticles; plant extract; antibacterial properties.

## 1. Introduction

The use of silver nanoparticles (AgNPs) in various fields has recently been increasing especially in textiles, medical, and foods because of their attractive features [1-5]. Their antimicrobial properties have been tested against bacteria, viruses, and fungi [6-8]. Nanoparticle synthesis typically uses physical approaches such as thermal decomposition and thermal/laser ablation or by a chemical such as electrochemical precipitation, sol-gel process, and aerosol pyrolysis. Alternatively, it can also be carried out using biological approaches by plants, bacteria, fungi, algae, and yeast. Biological approaches are considered as eco-friendly and economically feasible methods compared to physical and chemical [9].

The physical process involved high energy consumption. In contrast, chemical processes involved toxic chemicals, which can pose unfavourable effects on the environment.

The minimisation of physical and chemical processes can reduce the cost. Thus, the benefits of using plant extract are because it is cleaner and it provides accessible, safe and non-toxic compounds [10]. Previous studies on plant extract include cashew tree (*Anacardium occidentale*) gum [11], purple heart plant (*Tradescantia pallida*) [12], cinnamon (*Cinnamomum cassia*) [13], sweet pepper (*Capsicum frutescence*) [14], boldo (*Peumus boldus*) [15], clammy cherry (*Cordia obliqua Willd*) [16], and kerson (*Muntingia calabura*) [17].

*Muntingia calabura*, is commonly called as *pokok ceri* or *kerukup siam* and can be found in Malaysia. It is a fast-growing tree that is wildy grown in the Southern and Northern America and South East Asia [18]. It is traditionally used as a folk remedy for the treatment of fever, incipient cold, liver disease, and antiseptic agent in Southeast Asia [19]. However, the effectiveness of the use of these plant extracts as reducing and stabilizing agents has not been investigated.

In closing the research gap, this study was aimed to investigate the green synthesis of AgNPs using aqueous *Muntingia calabura* leaf extract as reducing and stabilising agents. Investigation on its bio-reduction reaction was conducted by using UV-Visible spectroscopy technique. The synthesized AgNPs were successfully characterised using FTIR, SEM, HRTEM, and XDS. In the application, antibacterial activities of AgNPs were tested against Gram-positive and Gram-negative bacteria.

## 2. Materials and Methods

### 2.1. Materials.

Silver nitrate ( $\text{AgNO}_3$ ), nutrient agar, Luria Bertani (LB) broth, and Whatman No.1 filter paper were acquired and used for experimental analysis. Two bacteria, *Escherichia coli* (*E. coli*) and *Bacillus cereus* (*B. cereus*) were obtained from the Faculty of Biomedical and Engineering (FBME), UTM. Both bacteria were maintained in nutrient agar media and Luria Bertani (LB) broth.

### 2.2. *Muntingia calabura* leaf extract preparation.

The fresh leaf of *Muntingia calabura* (*M. calabura*) was obtained to biosynthesize the silver nanoparticles. The preparation of leaf extract was adapted from previous studies with a little modification [20,21]. Fresh leaves of *M. calabura* were collected and washed thoroughly using tap water twice and by deionized water to remove dirt and debris. The cleaned leaves were dried under the shed and finely cut using a clean scissor. Twenty (20) grams of the leaf was added into 500 mL of deionized water and heated at 60 °C for 30 min. This was followed by cooling at room temperature. It was further filtered through Whatman No. 1 filter paper using vacuum filtration system. The filtered leaf extract was stored at 4 °C for further analysis.

### 2.3. Synthesis of AgNPs.

In the biosynthesis process of AgNPs, the effects of the quantity of fruit extract and concentration of  $\text{AgNO}_3$  were assessed to intensify the synthesis route in producing the metal nanoparticles. The aqueous solution of  $\text{AgNO}_3$  (0.01 – 0.03 M) was used and the volume of the aqueous fruit extract was added at 1:1 ratio (v/v). The mixture was left under dark condition with stirring using magnetic stirrer for 24 h. As a comparison to show that the AgNPs synthesis was mediated by phytochemicals of *M. calabura* leaf extract, a control flask containing

aqueous solution of AgNO<sub>3</sub> and deionized water was also used and kept under the same condition as the AgNPs synthesizing mixture. The occurrence of silver ions reduction was observed when the mixture optical colour changed from clear brown to dark brown solution. The optical density developments were monitored and measured timely for 1 h and up to 48 h using spectrophotometer (Macherey-Nagel Nanocolor UV/Vis).

#### 2.4. AgNPs characterization.

Biosynthesized AgNPs consequent of reduction of silver metal ions with aqueous *M. calabura* leaf extract was observed by a spectrophotometer (Macherey-Nagel Nanocolor UV/Vis) it was operated at 1 nm resolution and wavelength of 200–800 nm. In addition, Energy dispersive spectroscopy (EDS, Oxford Instruments, Oxford, United Kingdom) confirmed the presence of AgNPs elements at 20 keV. Moreover, the morphology of AgNPs was structurally characterized in high resolution mode (HR-TEM) using JEOL-ARM200F model instrument. The FTIR analysis was also performed to determine the presence of possible compounds that act as capping and stabilizing agents for the AgNPs in the range from 400 to 4000 cm<sup>-1</sup>. The analysis was performed using FTIR spectrometer (PerkinElmer Frontier-GPOB model 96046).

#### 2.5. Antibacterial activity of AgNPs.

The antibacterial activity of the biosynthesized AgNPs was evaluated against *E. coli* and *B. cereus* by paper disc (6 mm diameter) method adopted from [1]. An overnight grown of *E. coli* and *B. cereus* culture (optical density (OD<sub>600nm</sub>) ≈ 0.8 @ approximately 1 × 10<sup>8</sup> CFU/mL) was used. Five millilitres (5 mL) of bacterial culture was spreaded over Mueller-Hinton agar plate. Paper discs were prepared by soaking it in respective AgNPs labelled as 0.01M, 0.02M, 0.03M, 9:1 and 1:9. The paper discs were air dried under laminar flow then transferred onto the prepared agar plates. Blank paper discs were soaked in filter sterilized deionized water. The plates were incubated at 30 °C for 24 h. Each bacterial plate was made in triplicates. The antibacterial activity was determined by averaging the diameter of the inhibition zone observed around respective paper discs.

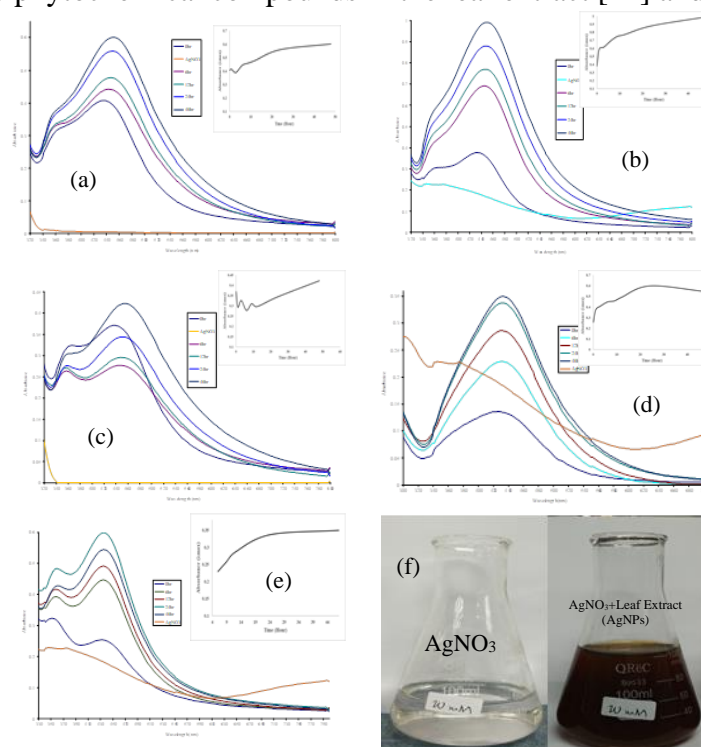

### 3. Results and Discussion

#### 3.1. UV-Vis spectroscopy of AgNPs.

The reaction of leaf extract with AgNO<sub>3</sub> was performed using different concentrations of AgNO<sub>3</sub>; 0.01M, 0.02M, 0.03M, and two ratio of AgNO<sub>3</sub> (0.01M) and extract which were 9:1 and 1:9. Figure 1 represents the rapid UV spectrum of AgNPs development when using AgNO<sub>3</sub>. After 1 h, rapid change of colour was clearly observed from colourless to dark brown as seen in Figure 1 (f). The AgNPs synthesis was confirmed by the UV-Vis spectrum of surface plasmon resonance (SPR) at 425–430 nm of adsorption band. It was noticed that at each condition, the longer the incubation time, the higher the UV-Vis wavelength adsorption but with different intensity. Steady development of AgNPs was indicated by the straight line of increment  $\lambda_{\max}$  as shown in Figure 1.

Narrow SPR peak at 425–430 nm was observed at 0.02 M of AgNO<sub>3</sub> with highest  $\lambda_{\max}$  of 0.991 as depicted in Figure 1. The absorbance intensity showed a significant decrease when the reaction is performed at a concentration of 0.01 and 0.03 M as well as 9:1 and 1:9 (v/v). This was due to agglomeration which was faster at concentration of 0.01 M and 0.03 M making

the SPR shifts and broadening the wavelength. This indicated that particle formation was influenced by the concentration of precursor and the size, shape and surrounding medium. This is referred to as the phytochemical compounds in the leaf extract [22] and [17].

**Figure 1.** UV-Vis spectra of AgNPs at (a) 0.01 M, (b) 0.02 M, (c) 0.03 M, (d) leaf extract: 0.01 M AgNO<sub>3</sub> ratio 9:1 and (e) leaf extract: 0.01 M AgNO<sub>3</sub> ratio 1:9 as well as (f) the colour changes of AgNO<sub>3</sub> solution after leaf extract addition.

### 3.2. FTIR analysis.

The FTIR was performed to identify functional groups that exist in the leaf extract of *M. calabura* and on the surface of AgNPs synthesized using the extract. These functional groups are responsible for the reduction of AgNO<sub>3</sub> to Ag<sup>0</sup>, capping and stabilization of silver nanoparticles in the solution. Figure 2 shows the FTIR spectrum of *M. calabura* leaf extract (b) and its AgNPs (a). The infra-red (IR) bands of 3307.92 cm<sup>-1</sup> are characterized as -OH, -NH, -CH of alcohol, aliphatic primary amine and alkyne. The band of 1637.56 cm<sup>-1</sup> indicated -C=C and -NH<sub>2</sub> of amide and amine group, mainly from protein compound. The compounds contained in the leaf extract are flavonoid, polyphenol and terpenoid [17]. A systematic literature study by [23] on *M. calabura* possesses a high content of antioxidant phytochemicals including terpenoids, flavonoids, tannins, and phenols which are beneficial for pharmacological activities. These compounds act as reducing agents. Meanwhile, the IR spectrum for AgNPs shows that the IR band of 2355.08 cm<sup>-1</sup> was absent. The band supposedly of -C≡N (nitriles group) and P-H ester stretching. This suggests that the functional groups are responsible for stabilizing and capping the AgNPs. It is further suggested that the protein structures in *M. calabura* extract are intact due to interaction with Ag<sup>+</sup> ions or nanoparticles [24]. The IR bands in 619 – 542 cm<sup>-1</sup> correspond to S-S and C-S stretching.

Interestingly, many previous researchers highlighted the significant antioxidant activity played by terpenoids. Quercetin in Tulsi plant extract (*Ocimum sanctum*) as one type of terpenoid [25], was reported as the main compound reacting with Ag<sup>+</sup> ion in synthesizing AgNPs. The terpenoids in geranium leaves were reported as the active compound in reducing the silver ions to AgNPs [26].

**Figure 2.** FTIR spectra of (a) *Muntingia calabura* leaf extract and (b) AgNPs.

### 3.3. Morphology, size, and EDS analyses.

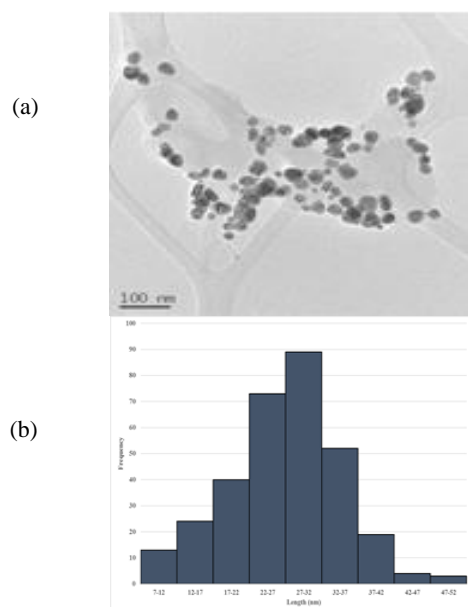

The surface morphology and size of AgNPs provided by SEM image showed that the AgNPs synthesized with diameter ranged from 30–60 nm in size. The AgNPs were scattered evenly as indicated by Figure 3. The large distribution of AgNPs diameter size was as a result of various phytochemical compounds in *M. calabura* leaf extract that act as reducing and capping agents [17].

**Figure 3.** SEM image of synthesized AgNPs at 10kV at 100000 × magnification.

TEM images which clearly show that the synthesized AgNPs were poly-dispersed in spherical shapes (Figure 4(a)). The diameter length or size distribution ranged from 7 to 52 nm (Figure 4(b)). The high frequency of size was within 22 to 37 nm. The EDX instrument further confirmed the Ag element in the synthesized AgNPs. This elemental analysis also confirmed the existence of other elements such as C, O, and P that are determined and shown in functional

groups from previous FTIR analysis. Thus, it proved that the AgNPs can be successfully synthesized using the *M. calabura* leaf extract and the AgNPs have been capped or encapsulated with various phytochemicals contributed by the *M. calabura* leaf extract. The inset SAED image of TEM of nanoparticles is presented in Figure 4(a). Bright diffraction spots in each image indicated that the silver nanoparticles are of single crystal quality [27], with polycrystalline nature [28].

**Figure 4.** (a) TEM images of AgNPs mediated by *M. calabura* leaf extract and (b) AgNPs size distribution.

Further confirmation on the elements which exist in the AgNPs was conducted. It was based on the EDS spectrum it is confirmed the Ag element that existed in the synthesized AgNPs. Other significant elements that co-existed are C, O, P and S as shown in Figure 5. All these elements were determined and shown in functional groups from previous FTIR analysis (Figure 2). This indicated that the AgNPs were well capped/encapsulated with various phyto-compounds originated from the *M. calabura* leaf extract.

**Figure 5.** EDS spectra of the synthesized AgNPs.

### 3.5. Possible mechanism of AgNPs synthesis.

Currently, there is a clear explanation on reduction of silver ions into AgNPs by phytochemicals, flavonoid, polyphenol and terpenoid in plant extract [17]. These compounds act as reducing and capping agents [29]. The -OH functional groups as depicted in Figure 6

reacted with  $\text{Ag}^+$  and reduced it into AgNPs. Figure 6 demonstrated the generation of two proton i.e., a quercetin molecule for the reduction of Ag ions via reduction-oxidation reaction.

**Figure 6.** Silver ions reduction by terpenoid (quercetin) molecule adapted from [25].

### 3.5. Antibacterial activity of AgNPs.

Based on the antibacterial activity, AgNPs synthesized from 0.02M  $\text{AgNO}_3$  showed a better inhibition activity against both *E. coli* and *B. cereus* compared to other concentrations of  $\text{AgNO}_3$  as shown in Table 1 and Figure 7. There is significantly different in bacterial inhibition efficiency between AgNPs from 0.02 M and other concentrations. For example, in *E. coli* inhibition, AgNPs from 0.01 M  $\text{AgNO}_3$  was inefficient by 17% and 10% from 0.03 M  $\text{AgNO}_3$ . Growth inhibition by AgNPs from different mixture ratio of leaf extract and 0.01 M  $\text{AgNO}_3$  was lower than the pure concentration of  $\text{AgNO}_3$ . This was due to the fact that the leaf extract at 90% was not able to act as antibacterial agent. The leaf extract at 10% volume synthesized lower intensity of AgNPs which is insufficient to suppress the growth of bacteria. The AgNPs killing mechanism is still specifically uncertain. However, there are research findings which highlighted that bacterial cell membrane interacts with AgNPs due to the existence of S and P constituent. Subsequently, this interaction can initiate the killing by interrupting the bacteria cell division and respiratory chain [30].

**Table 1.** Zone of inhibition of AgNPs by *M. calabura* leaf extract.

AgNPs	Zone inhibition $\pm$ SD (mm)	
	<i>E.coli</i>	<i>B. cereus</i>
0.01	8.3 $\pm$ 0.6	9.0 $\pm$ 1.0
0.02	10.0 $\pm$ 1.0	9.7 $\pm$ 0.6
0.03	9.0 $\pm$ 1.0	7.7 $\pm$ 0.6
1:9	8.3 $\pm$ 0.6	7.3 $\pm$ 0.6
9:1	8.0 $\pm$ 1.0	8.3 $\pm$ 0.6

**Figure 7.** Zone of inhibition of AgNPs against (a) *B.cereus* and (b) *E. coli*.

## 4. Conclusions

The aim of this study was to investigate the green synthesis of AgNPs using aqueous *Muntingia calabura* leaf extract as reducing and stabilising agents. The FTIR analysis revealed that the phytochemicals in *M. calabura* are flavonoid, polyphenol, and terpenoid. The

morphological observation confirmed the poly-dispersed spherical shape and size ranging from 22 to 37 nm. The polycrystalline nature of the synthesized AgNPs was confirmed by the TEM analysis. The AgNPs synthesized using 0.02 M AgNO<sub>3</sub> were the most efficient in inhibiting all bacterial growth. In general, findings from this work confirmed that the *M. calabura* leaf extract has the potential as the biological alternative for AgNPs production.
