Abstract: Gongronema latifolium is a tropical plant with verse traditionally and medicinal uses in mostly Africa and Asia. In this work, we determined the biochemical effects of G. latifolium ethanolic extracts in male Wistar rats. The G. latifolium stem and leaves were air-dried separately, macerated, and extracted in 80 % ethanol. The Wistar rats were assigned into three groups randomly; control was administered distiller water, the treatment groups respectively were given 200 mg/kg bw of the extracts of leaves or stem for twenty-eight (28) days. Data showed that the rat serum ALT and ALP activities were lower in the extract-treated group than in the control group administered distilled water. In the rat liver, there were significant differences (p<0.05) in biochemical parameters compared to the control group as the extract-treated group showed a reduction in ALT, AST, and ALP activities. Meanwhile, the oral administration of the G. latifolium extracts led to the elevated (p<0.05) level of serum urea, while the serum triglycerides and creatinine levels were reduced compared with the control. Together, the data suggest that G. latifolium extracts at the doses tested had minimal renal toxicity.

1. Introduction

Gongronema latifolium, also known as the Amaranth globe, is native to the tropics and is readily found in West Africa. The plant is of the family Asclepiadaceae and belongs to the genus Gongronema [1-3]. The G. latifolium is edible, and when consumed fresh, it gives a sensational taste that is sour and mildly pleasant [4-7]. Additionally, G. latifolium is acclaimed not only to be nutritious but medicinal [8]. For example, G. latifolium is richly nutritive with many lipids, proteins, amino acids (essential and non-essential), vitamins, and mineral elements [8-11]. Also, the dry matter of G. latifolium has been shown to contain tangible levels of essential fatty acids such as linoleic acids [12]. Linoleic acid is a precursor to arachidonic acid,
and it forms a significant part of the membrane phospholipids [12]. Furthermore, *G. latifolium* leaves have been implicated in possessing mineral elements such as sodium, calcium, potassium, iron, and magnesium [11].

The *G. latifolium* is used for medicinal purposes [13, 14]; traditionally, the plant infusion and/or decoction is applied to treat digestive challenges such as indigestion, abdominal ache, lack of bowel movement, diarrhea as well as intestinal parasites [9, 10]. Additionally, the *G. latifolium* is part of the decoction usually applied to help detoxify and restore the liver in hepatitis patients [15]. In separate reports, the *G. latifolium* has been used to treat hyperglycemia and hypertension, hepatitis and alcohol-induced liver damage [16], as well as womb cleansing and abdominal pain after childbirth [10]. The leaves used in cooking have also been potent in relieving cold and loss of appetite [17]. In the present investigation, the biochemical toxicity of the extracts of the *G. latifolium* was determined in male Wistar rats. This is to ascertain the safety of its consumption and usage in alternative medicine. This will further serve as a guideline to the consumption and usage of *G. latifolium*.

2. Materials and Methods

2.1. Assay kit for the metabolites and enzyme assay.

Assays of alkaline phosphatase (ALP), alanine aminotransferase (ALT), aspartate aminotransferase (AST), creatine, triglycerides, cholesterol, bilirubin, albumin, and urea were performed using reagent kits gotten commercially (Randox Laboratories Limited, Crumlin, UK).

2.2. Extract preparation from Gongonema latifolium.

The fresh whole plant part of *Gongonema* (stem and leaves) were collected respectively from the Flower garden and Sanrab within the Ilorin metropolis of Kwara state in Nigeria. The plant was validly identified with a voucher number UILH/001/855 at the Herbarium unit of the Plant Biology department, University of Ilorin, Nigeria. The stem and leaves of the *Gongronema* were washed and air-dried. After that, the plant leaves and stem were pulverized and extracted with 80 % ethanol for 72 h at 4°C. The extracts were filtered using a muslin cloth and concentrated using a rotary evaporator (Buchi Rotavapor - R110) at reduced pressure at 55°C.

2.3. Experimental animals.

Nine (9) male Wistar rats of average weight 110±35g were obtained from the animal unit of the Department of Biochemistry, University of Ilorin, Nigeria. The male rats were identified through physical observations and were used to avoid the hormonal interactions caused by the estrus cycle in females. The Wistar male rats were accommodated in well-ventilated plastic cages with sawdust as beddings and kept in standard laboratory conditions (12-hour light and dark cycle, 25±2°C). The rats were sustained on standard rat pellets, and they were given unrestricted access to clean water. The handling of rats was under the guidance of the Laboratory Animal Ethics Committee of the University of Ilorin. This was consistent with the NIH guide for the care and use of laboratory animals [18]. The rats were acclimated for two weeks before the experimental treatments commenced.
2.4. Experimental grouping and treatments.

The rats were grouped randomly into three (3) rats per group. The control group was given distilled water only, while the treatment groups respectively received either the ethanolic extracts of *G. latifolium* stem or leaves (0.4 mg/kg bw) re-suspended in distilled water. The treatments were daily and orally administered for twenty-eight days.

2.5. Necropsy.

After the last treatment, the rats were sacrificed after an overnight fast using anaesthetization mildly with diethyl ether. Blood samples were then collected into sterile bottles by incising the jugular vein, while the vital organs such as liver, heart, and kidney were then excised, weighed, and homogenized in isotonic sucrose solution (0.25 M). The homogenates were stored frozen at -4 °C until used for biochemical assays.

After 30 min at room temperature, the blood samples were centrifuged for 10 min at 1000 g (Uniscope Model SM800B, England, UK). The supernatant was collected using Pasteur’s pipette and stored frozen at -4 °C until used for the biochemical assays.

The determination of the rat serum and total tissue protein (TP), albumin, AST, ALT, ALP, bilirubin, urea, creatinine, and triglycerides were carried out by using commercial assay kits (Randox, Crumlin, UK).

2.7. Statistical analysis.

The data obtained were analyzed using a one-way analysis of variance (ANOVA) on SPSS (IBM, USA). Duncan Multiple Range test was applied for the posthoc analyses, and the results are presented as mean ± standard error of the mean (SEM, while mean values at \( p < 0.05 \) are significant.

3. Results and Discussion

The percentage yield of *G. latifolium* ethanolic extracts was 11.97% for the leaves and 9.61% for the stem. Meanwhile, the oral administration of the ethanolic extracts caused no weight change in the average rat weight and the organ to rat weight ratio after 28 days of administration (Figures 1-3).

The rat liver AST activity in ethanolic extract-treated groups decreased when compared with control (Figure 4). The rat serum and heart AST levels were elevated compared with control. However, the rat tissue and serum ALT levels in treated groups had no appreciable changes compared with control (Figure 5). Conversely, the rat kidney, heart, and serum ALP levels in rats treated with ethanolic extracts of *G. latifolium* leaves were increased when compared with control (Figure 6). The levels of rat serum urea increased \( (p < 0.05) \) when in comparison with the control. However, the serum's bilirubin, creatinine, and albumin levels had no appreciable change compared with the control (Figure 7). Additionally, the oral administration of the ethanolic extracts of *G. latifolium* caused a reduction \( (p < 0.05) \) in rat serum triglycerides.

3.1. Discussion.

Numerous recent investigations have been seeking possible ways to harness natural products as alternative treatment strategies, especially from plants with a proven traditional history of medicinal value [19-23]. The *G. Latifolium*, is a perennial plant used for domestic and medicinal purposes, predominantly in eastern Asia and West Africa [24, 25]. With its popular and common usage in these regions, the need to profile the plant for safety and/or toxicity is imperative. In this present work, we determined the biochemical toxicity of *G. latifolium* in Wistar rats. Data showed that the ethanolic extracts of *G. Latifolium* leaf and stem did not cause alterations in the rat body and organ weights compared to control. This finding seems to agree with previous studies showing the nutritional value of *G. Latifolium* [12]. The evaluation for rat liver toxicity showed that the ethanolic extracts of *G. Latifolium* leaves and stem did not cause hepatotoxicity; liver function indices such as ALT and AST have not elevated appreciably compared with control. Additionally, rat serum bilirubin and albumin levels were comparable to those of the control, suggesting the absence of hepatic assault. However, the reduced levels of AST, ALT, and ALP activities after oral exposure to the ethanolic extracts of *G. latifolium* might be due to the potential of the extract or its metabolite to inhibit the activities of these enzymes. Conversely, an increase in rat heart AST, ALP, and ALT levels may denote the potential of *G. Latifolium* to predispose to cardiovascular perturbations [26, 27].

Furthermore, we determined rat serum urea and creatinine levels to ascertain kidney function. The ethanolic extracts increased rat serum urea levels compared with control. The increase in serum urea levels might indicate the ensuing impairment of kidney function [28, 29]. Previously, reports demonstrated the hepato-renal toxicities of *G. latifolium* in rats [23]. The decreased triglyceride level in rat serum might be due to the gastric emptying effect of *G. Latifolium*, as was previously shown elsewhere [30]. Also, *G. Latifolium* has been reported to contain niacin, which may interfere with lipid metabolism by inhibiting hormone-sensitive lipase and prevent hepatic VLDL synthesis, thus decreasing triglycerides and LDL while increasing HDL levels [31-35].
4. Conclusions

In conclusion, our findings suggest that the administration of ethanolic extracts of *G. Latifolium* might not have caused liver injury at the doses investigated. Conversely, the ethanolic extracts caused mild renal disturbances as reflected in an elevated serum urea level. Additionally, the reduction in the rat serum triglyceride level by the ethanolic extracts may indicate a potential benefit for cardiovascular functioning.
