Abstract: Acne is a chronic inflammatory skin disorder that involves the pilosebaceous unit. It is a common universal disease affecting about 85% of teenagers. The disfiguring dermatosis of acne can destroy self-confidence, causing significant emotional distress. Topical and systemic therapies are available as a conventional acne treatment, including comedolytic agents, antibiotics, and various anti-inflammatory drugs. Interest in medicinal herbs has been progressively increasing due to antibiotic resistance in acne-causing bacteria, side effects, and sometimes high cost of conventional treatment. This review provides up-to-date evidence on medicinal plants and the phytoconstituents used in acne treatment. The data presented in this review were gathered from several databases, including Pubmed, Wiley Online Library, Elsevier, and Web of Science, using keywords such as; Acne vulgaris, Cutibacterium acnes (formerly Propionibacterium acnes), skin diseases, medicinal plants, active constituents, complementary and alternative medicines. The present manuscript provides an updated review of the most reported active constituents with anti-acne properties. Among these classes were the phenolic compounds, exemplified by anthraquinones, flavonoids, tannins, alkaloids, certain terpenes and oxygenated terpenes present in the essential oils of many medicinal plants.

Keywords: Acne vulgaris; Cutibacterium acnes; Propionibacterium acnes; Staphylococcus epidermidis; skin diseases; medicinal plants; essential oils; antimicrobial activity; antibiotic resistance.

1. Introduction

*Acne vulgaris* is a disfiguring prolonged inflammatory disorder of the pilosebaceous units. The psychological impacts of acne include loss of self-confidence, depression, anxiety, and interpersonal and work-related difficulties. The clinical presentation of acne comprises black and whiteheads (comedones), pinheads (papules), pustules, nodules, and pitted or hypertrophic scars [1]. The face, shoulders, upper chest, and back may be affected [2].

*Acne vulgaris* is mainly attributed to the increased production of androgens present in males and females during puberty. Accordingly, the pilosebaceous units produce more sebum, followed by follicular hyperkeratinization and plugging of the hair follicles. Thus, sebum cannot reach the skin surface, which encourages anaerobic bacteria, including Cutibacterium acnes (formerly Propionibacterium acnes), to grow in the plugged follicle. These bacteria trigger an inflammatory response in the skin, manifested as heat, swelling, redness, and pus [3].
The Global Burden of Disease (GBD) reported in 2010 that *Acne vulgaris* was the eighth most common skin disease, with an estimated global prevalence (for all ages) of 9.38% [4]. It affects more than 85% of teenagers, and boys most frequently have severe forms of the disease [5]. More than 100 million US dollars are spent on over-the-counter acne products [6]. Acne is a multifactorial disease affected by interacting factors, and the main risk factors are summarized in figure 1 [7].

![Figure 1. Predisposing factors of Acne vulgaris.](image)

Acne treatment aims to control existing lesions, prevent permanent scarring as far as possible, limit the duration of the disorder, minimize morbidity and guard against the formation of new acne lesions. Anti-acne drugs may act by normalization of follicular keratinization, thus suppressing sebum production. Others exert antibacterial action against *Cutibacterium acnes*, alleviating inflammation and, through the antioxidant effect, reducing oxidation of sebum, which favors the growth of *C. acnes*. Conventional acne treatment involves topical alone or in combination with systemic therapies in severe cases. Topically used agents include comedolytic agents, antibiotics, and various anti-inflammatory drugs. Systemically used agents include retinoids, antibiotics, zinc, and hormones [8]. Topical treatment is the standard for most patients with comedo-papular acne; however, local and systemic treatments are needed for pustulocystic scarring acne [9]. Drawbacks of conventional therapy include increased antibiotic resistance in acne-causing bacteria (*C. acnes* and *S. epidermidis*) [9]. Moreover, the increased incidence of pregnant women exposed to oral tretinoin, a known teratogen [10], and the poor safety profile of systemic retinoid therapy [9,11].

Herbal therapy of acne has been encouraged due to the advantages of better patient tolerance, long history of use, fewer side effects, and being relatively more cost-effective. Many herbs with a history of use in traditional cultures have entered the growing ‘cosmeceuticals’ market. The efficacy of herbs used in acne treatment is due to their...
antibacterial activity and their influence on sebum activity, inflammation, and hyperkeratinization associated with acne. This review aspires to provide up-to-date evidence on medicinal plants and the phytoconstituents used in acne treatment.

2. Materials and Methods

The data presented in this review were assembled from several databases, including PubMed, Wiley Online Library, Elsevier and Web of Science Core Collection, and digital search platforms. The search terms were *Acne vulgaris*, acne, anti-acne, *C. acnes*, skin diseases, medicinal plants, herbal medicines, phytotherapy, Ayurveda, Unani, and Chinese traditional medicine. Additionally, the reference lists of articles were reviewed for additional relevant studies.

3. Results and Discussion

Many efforts have been made to study medicinal herbs' anti-acne activity and investigate the phytoconstituents responsible for that activity. The following part compiles the medicinal plants used in acne treatment, classified according to the class of their active constituents.

3.1. Phenolic compounds.

Phenolic and polyphenolic constituents contribute to vital processes of plant physiology. Phenolic compounds demonstrate activity against *C. acnes* via their antimicrobial, antioxidant, and anti-inflammatory properties, thus exhibiting an anti-acne effect. Table 1 summarizes studies on herbs containing anti-acne phenolic compounds and their mode of anti-acne action.

3.2. Terpenoids and steroids

Terpenoids represent the largest and most diverse group of naturally occurring plant secondary metabolites. The role of terpenoids in acne may be due to their antibacterial activity against *Cutibacterium acnes*, anti-oxidant or anti-inflammatory activity. Table 2 summarizes herbs containing anti-acne terpenoids, steroids, and their reported mode of action.

### 3.3. Alkaloids.

Alkaloids are a major class of phytoconstituents and have been well studied for acne treatment (Table 3). Berberine has been reported to exhibit antimicrobial activity against *Cutibacterium acnes*, *Staphylococcus* spp., and decrease lipogenesis by sebaceous glands in hamsters [195].
3.4. Fatty acids.

Sebum secretion is one of the main factors of acne pathogenesis. Quantitative and qualitative alterations have been observed in sebum from acne patients. The C16 : 0/C16 : 1 ratio in the skin surface triglycerides and wax esters is higher in acne patients. It has been suggested that the desaturation of fatty acids may play a major role in sebogenesis and acne onset. It has been reported that linoleic acid is effective in acne treatment. In a double-blind placebo-controlled randomized cross-over study, topically applied linoleic acid significantly affected the size of follicular casts and microcomedones [207,208]. Therefore, plants containing linoleic acid may be used in acne treatment. Table 4 summarizes herbs containing fatty acids and their reported mode of action.

### Table 3. Herbs containing anti-acne alkaloids.

3.5. Miscellaneous constituents.

Some plants have been studied for their anti-acne activity due to their antimicrobial, anti-inflammatory, anti-androgen, and antioxidant activities. Their constituents belong to different chemical classes; these herbs are summarized in table 5; all these have anti-acne activities due to various constituents.

### Table 4. Herbs containing anti-acne fatty acids.

4. Conclusion

Conventional treatment of acne has been used for a long time. The extensive use of antibiotics led to the emergence of resistance in acne-related pathogens. Isotretinoin is effective in all stages of acne pathogenesis, yet it demonstrates various adverse effects and is teratogenic. Moreover, the high cost of conventional treatment of acne presents another drawback. Herbal
medicine has been used effectively since ancient times in acne treatment. The efficacy of such herbs is not only due to their anti-bacterial activity but also their influence on androgenicity, increased sebum activity, inflammation, and hyperkeratinization associated with acne.

Based on the above data, it could be deduced that the class of phenolic constituents demonstrated the highest anti-acne potential among the investigated phytoconstituents. The terpenoids followed this class, demonstrating promising activity against acne and acting by different mechanisms. As for the alkaloids, berberine was the most prominent from various plants with an anti-acne effect.

Many herbs with a history of use in traditional cultures have entered the growing ‘cosmeceuticals’ market due to the advantages of better patient tolerance, long history of use, fewer side effects, and being relatively more cost-effective. Herbal extracts may be used alone or as adjuvants. Novel drug delivery systems such as microemulsion, liposomal, and nano-formulations can improve the drug delivery of herbal extracts or oil to reduce their associated side effects. This creates extensive interest in developing such formulations, thus flourishing the pharmaceutical industry.

The present review provides extensive and updated research on the anti-acne properties of medicinal plants and their phytoconstituents. This work provides a useful bibliography for further preclinical and clinical investigations and encourages the pharmaceutical industry to invest in the natural treatment of acne projects.
